

ABSTRACT OF THE DISCLOSURE

The image forming apparatus includes a movable first image bearing member on which a toner image is formed, and a movable second image bearing member
5 which is brought into contact with the first image bearing member and to which the toner image on the first image bearing member is transferred, in which a dot-shaped dot image formed of a toner different from the toner image is formable on the first image bearing member, and in which a distance between dot centers of the dot images is equal to or smaller than a width of a contact part between the first image bearing member and the second image bearing member in a moving direction of the first image bearing member.
10 Consequently, it is possible to steadily suppress an image streak occurrence and to obtain a final image having a high quality in a stable manner.
